

Example 3.2

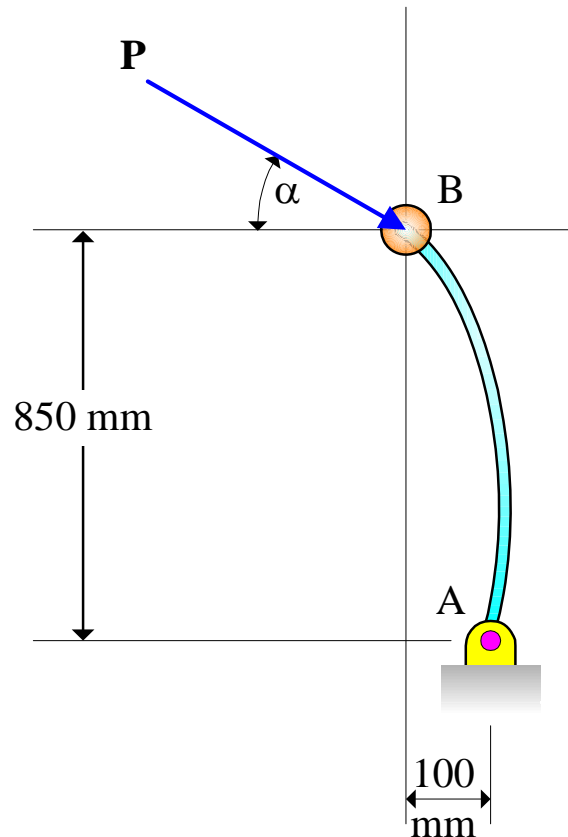

J. Frye

Example 3.2:

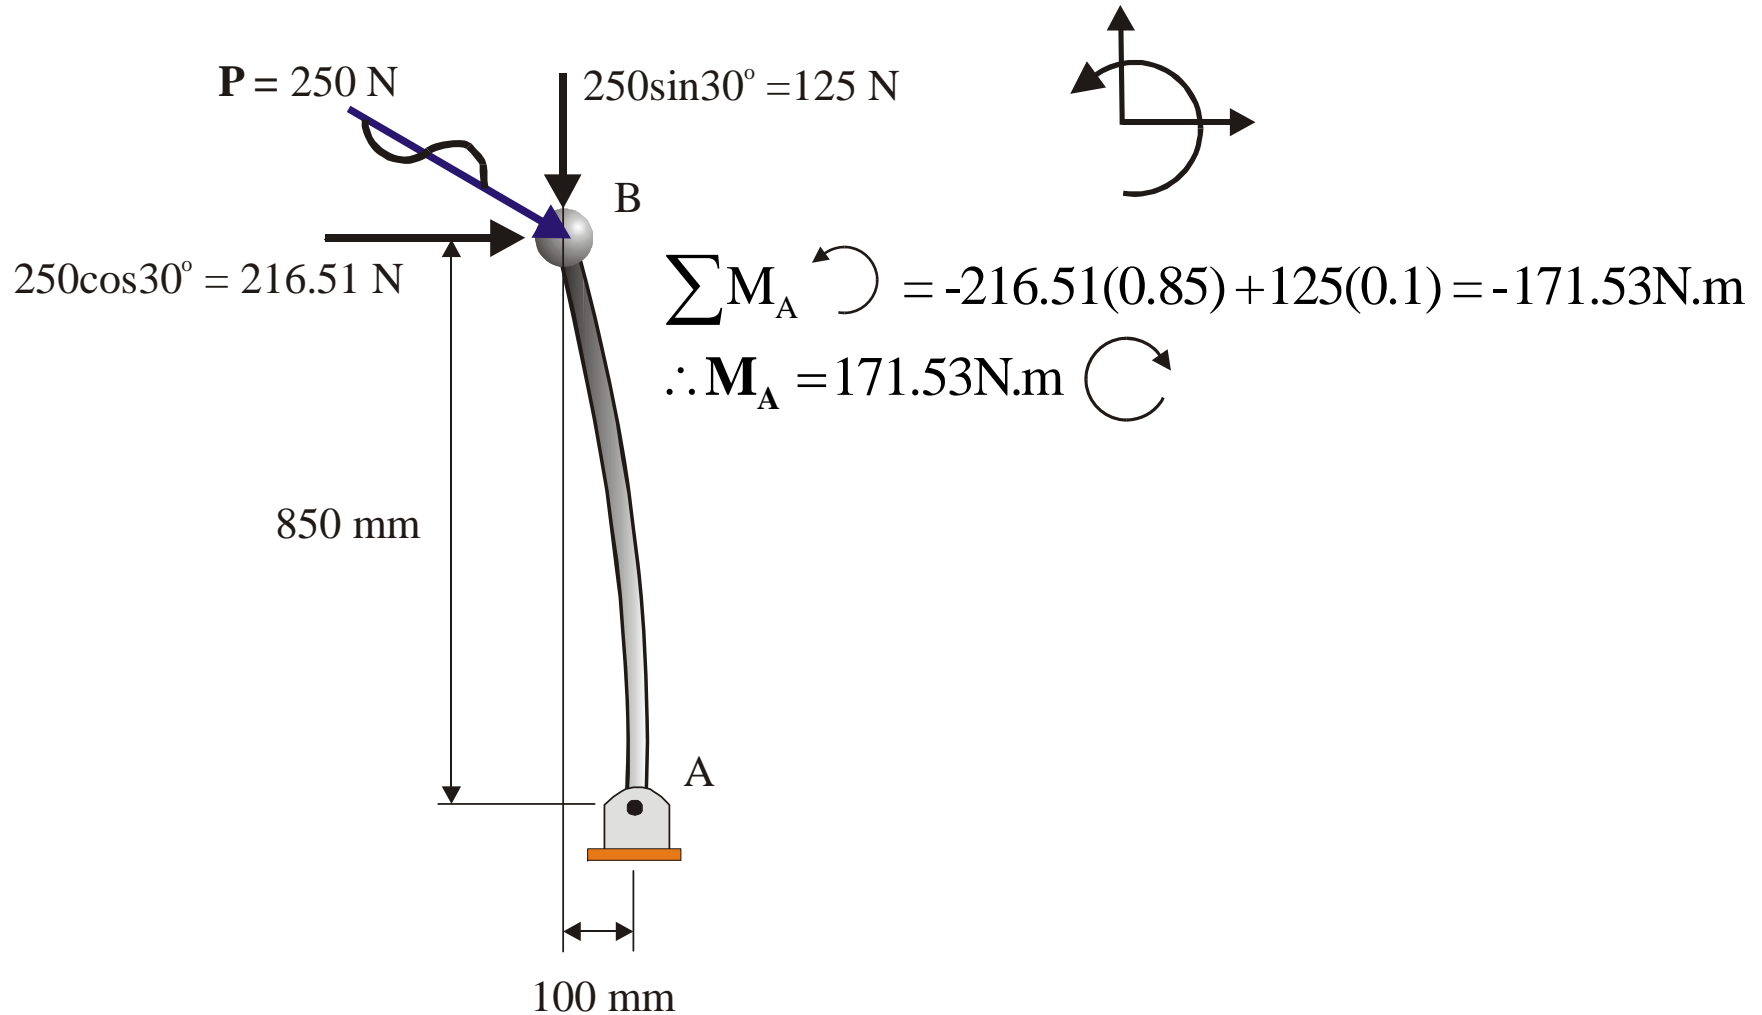

A force \mathbf{P} is applied at point B of the gear shift.

(a) Determine the moment of \mathbf{P} about point A when $P = 250\text{ N}$ and $\alpha = 30^\circ$.

(b) Find the smallest value P and angle α which has the same moment as in part (a).

a) We resolve force P into its Rectangular Components and take moments about A

b) Since $M = Fd$ or $F = M/d$

F gets smaller as d increases.

The minimum value of force **P** occurs when the perpendicular distance, d from the line of action of the force to the point we are taking moment about is the largest distance.

In this case, d = length of the line BA and **P** is perpendicular to this line

$$d = \sqrt{0.85^2 + 0.1^2} = 0.856\text{m}$$

$$M = Fd$$

$$171.53 = F(0.856)$$

$$F = 200.39\text{N}$$

$$\therefore \mathbf{F} = 200.39\text{N}$$
